parsePythonDocstring

Kind: Function

Source: atloria-monorepo/libs/parser-core/src/openapi/doc-annotations.ts

Parse a Python docstring: first line (or sentence) is the summary, the rest the description.

Sphinx/Google/NumPy section furniture is left in the description untouched — it is the author's text, the reader renders markdown, and rewriting it would be inventing prose.

`:param name: desc` is read because it is the one Python convention that names parameters precisely enough to attach without guessing.

Signature

```
function parsePythonDocstring(raw: string): AuthoredDocs
```

Parameters

Name	Type
raw	string

Returns: AuthoredDocs
