sanitizeForJsonb

Kind: Function

Source: [atloria-monorepo/apps/api/src/technical-docs/sanitize-jsonb.ts](https://github.com/atloria-monorepo/apps/api/src/technical-docs/sanitize-jsonb.ts)

Deep-sanitize a value before persisting it into a Postgres `jsonb` column.

Postgres `jsonb` cannot store the NUL character (U+0000) and chokes on other C0 control

characters. These leak in from parsed source (minified bundles, generated/binary-ish files)

and, at monorepo scale, a single bad byte deep in a multi-megabyte snapshot fails the whole

upsert with `unexpected end of hex escape`. Strip them (and lone UTF-16 surrogates, which are

not valid text) so the snapshot always persists. Tab / newline / carriage-return are kept.

Signature

```
function sanitizeForJsonb(value: T): T
```

Parameters

Name	Type
<code>value</code>	<code>T</code>

Returns: `T`
