SnapshotDiff

Kind: Interface

Source: `atloria-monorepo/apps/api/src/technical-docs/technical-docs-materializer.service.ts`

S4 (code → docs delta): bucket the NEW snapshot's page-backed entities against the stored

per-entity signature baseline (`technicalSnapshot.signatureHashes` , stamped at the last materialize — preserved across a re-parse because `upsertSnapshot` never writes it).

This is

the techdocs analog of the screenshot pipeline's `screen_diff` : only entities whose PUBLIC

contract moved need their page regenerated. Description/comment-only edits don't change

`signatureHashOf` , so they don't churn a page. `pageEntities` must already be the junk-filtered

set that actually produces a document (derive it from the rendered docSet), so the diff aligns

exactly with what gets materialized.
