System requirements

What you need to use Atloria

Atloria is a product-intelligence platform delivered through a web application.

Workspace access and repository setup are separate steps:

If you need to...	Go to
Understand what Atloria is	What is Atloria
Check the access state before opening the workspace	Before you start
Reach the workspace	Reach the workspace
Connect a repository	Connect a repository
Resolve an access or connection problem	When access or connection fails
Sign in and complete initial access	Your first day
Get help with an unresolved problem	Getting help

Before you start

Prerequisites

- An authenticated session is a signed-in workspace session.
- You have the repository information needed for the connection you are about to make.

An authenticated session is required to load project data.

With these prerequisites in place, continue to [Reach the workspace](#).

Reach the workspace

The workspace is the authenticated application area where the dashboard and project work are available.

Prerequisites

- You have an authenticated session.

Steps

1. Open the workspace and continue according to the page you reach:

If you see...	The application does...
The authenticated workspace	Shows Dashboard and loads project data for the authenticated session.
The sign-in page	The workspace is unavailable until the sign-in step finishes.

Result: You are on **Dashboard** when the session is active; otherwise, complete sign-in before continuing to repository setup.

Connect a repository

Repository authentication gives Atloria the credentials it needs when a repository is private or public access does not succeed.

Prerequisites

- You are signed in to the workspace.
- You have the repository credentials when public access is unavailable.

Steps

The application first tries public repository access without credentials. If that fails, it tries a connected provider. When those checks do not provide access, the authentication controls appear.

1. Select **Authentication**.
2. Enter the repository identity in **Username / Token Name**.
3. Enter the repository credential in **Password / Access Token**.
4. Select **Test Connection**.

The **Configuration** tab is also available during repository setup. The authentication fields are shown when repository authentication is needed.

Result: The connection check displays either `Connection successful` or a connection failure message.

When access or connection fails

Use the message on screen to choose the next action.

What you see	What it means	What to do
<code>7-day activity unavailable</code>	The dashboard's seven-day activity request failed.	Continue with the workspace and retry the activity request when the service is available.
<code>Provide credentials to access this repository. Required for private repos.</code>	The repository needs private-access details before the check can continue.	Open Authentication and provide the repository values in Username / Token Name and Password / Access Token .
<code>Connection test failed – check your credentials</code>	The repository could not be accessed with the entered details.	Check the values in Username / Token Name and Password / Access Token , then select Test Connection again.
<code>Connection failed</code>	The repository could not be reached with the current connection details.	Check the repository values and select Test Connection again.
<code>Connection successful</code>	The repository is ready for the next setup step.	Continue with the project configuration.

Continue with Atloria

After the environment check, continue with [Your first day](#) for account access, [What is Atloria](#) for product orientation, or [Getting help](#) for product questions and issues.
